# Learning Objectives

At the end of this presentation, you will be able to...

- Assess the geometry of the foundation for efficiency
- Evaluate the effects of different tendon layouts
- Understand the effects of stiffness relative to the concrete neutral axis and tendon placement
- Holistic view of construction practices relative to the overall value of the design

# Fundamental Drivers of SOG Performance

Independent from applied code, calculation method or soil conditions, the performance of two alternative designs can be evaluated using these factors:

- Bending Stiffness is the #1 determinant of performance
- Precompression provided by PT delays cracking and ensures inherent stiffness can be fully utilized
- Profiled PT can offset applied moments

# Parametric Study of Different Geometries

Keeping the moment of inertia stiffness constant, we compare the performance of three different shallow foundation configurations:

- Traditional ribbed slab
- Non collapsable void form foundation
  - 8.5 in
  - 12 in

# Sample Project

Common 40 ft x 70 ft footprint

PVR (inches)	Center Lift		Edge Lift	
	$E_m$ (feet)	$Y_m$ (in)	$E_m$ (feet)	$Y_m$ (in)
1	8.3	-0.96	4.2	1.33
4	6.1	-2.33	3.5	3.8

Loading:

-  1,200 plf around perimeter
-  40 psf interior live load

# Calibrated Models to Have Same Stiffness

Maintaining minimum stiffness in long direction was governing factor

Traditional –  
Plan View

# Observations

Even though the full cross-sectional moment of inertia was selected to be the same for all foundation models, their ultimate performance is impacted by their asymmetric geometry, precompression, tendon profiling and construction methods.

This concludes the Educational Content of this activity.
